Project Objectives

 Understand the affect of different antenna characteristics on the performance of Bluetoothbased data collection units.

Cost: ~ \$ 240 / unit

Single Antenna Testing Setup

- Test location Wallace Road in Salem, Oregon
 - Power source , mounting location (
 10 ft.), adjacent loop detectors, digital modem.

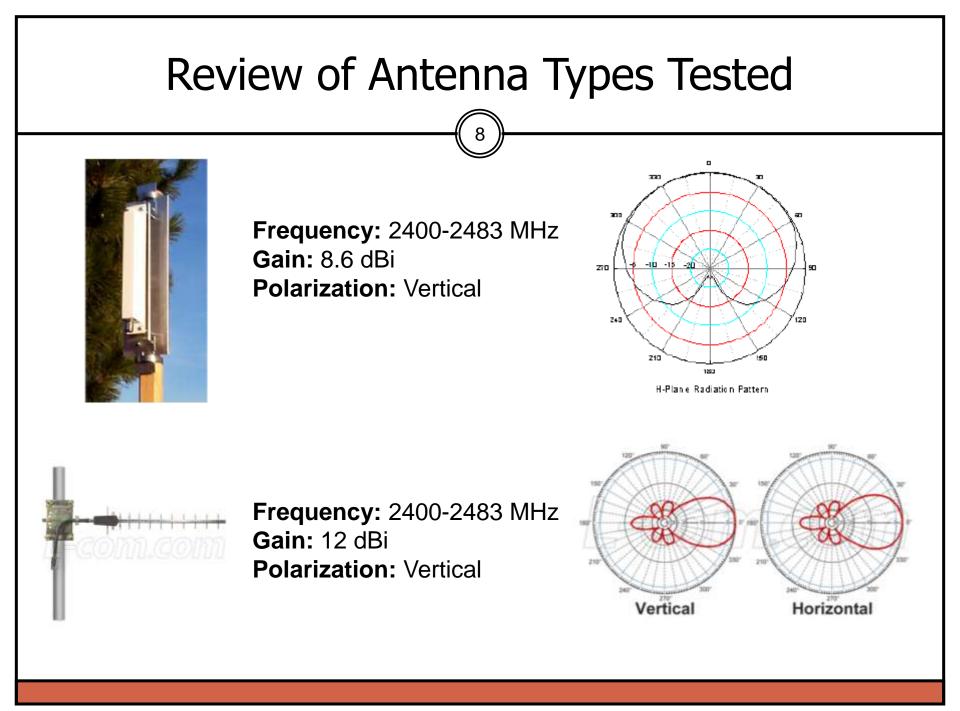

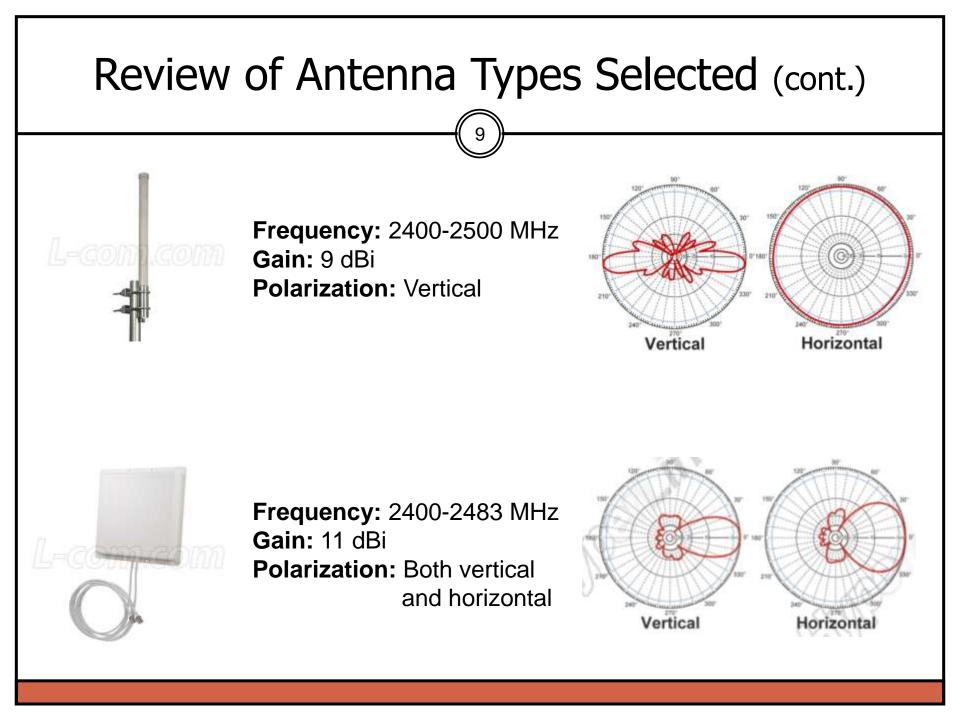

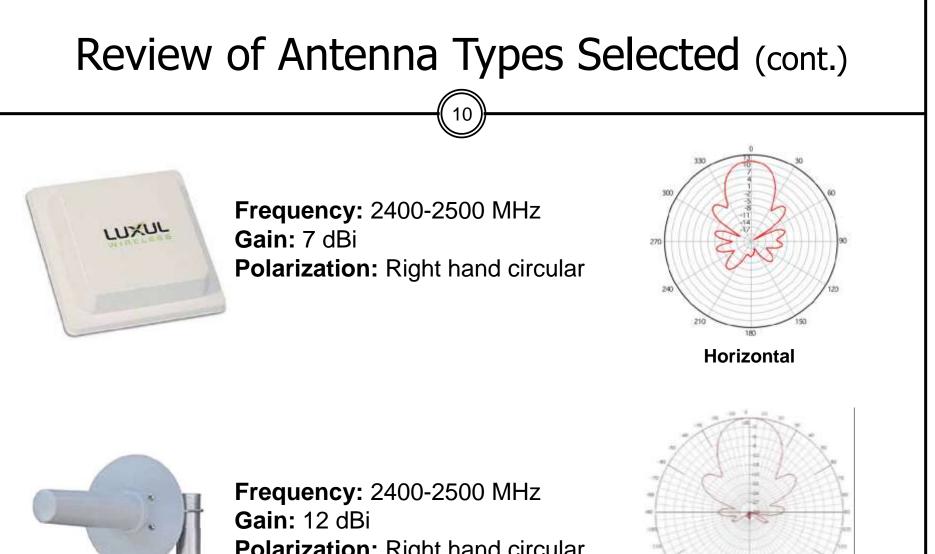

Antenna Types Tested

- Antenna types varied mainly on the following three characteristics
 - Gain
 - Polarization
 - Shape and size of the coverage patterns
- The ultimate objective was to determine whether or not the above factors had an impact on the performance of the Bluetooth readers
- Antennas were oriented to maximize road coverage

Horizontal

Polarization: Right hand circular

Experimental Design, Data Collection and Analysis

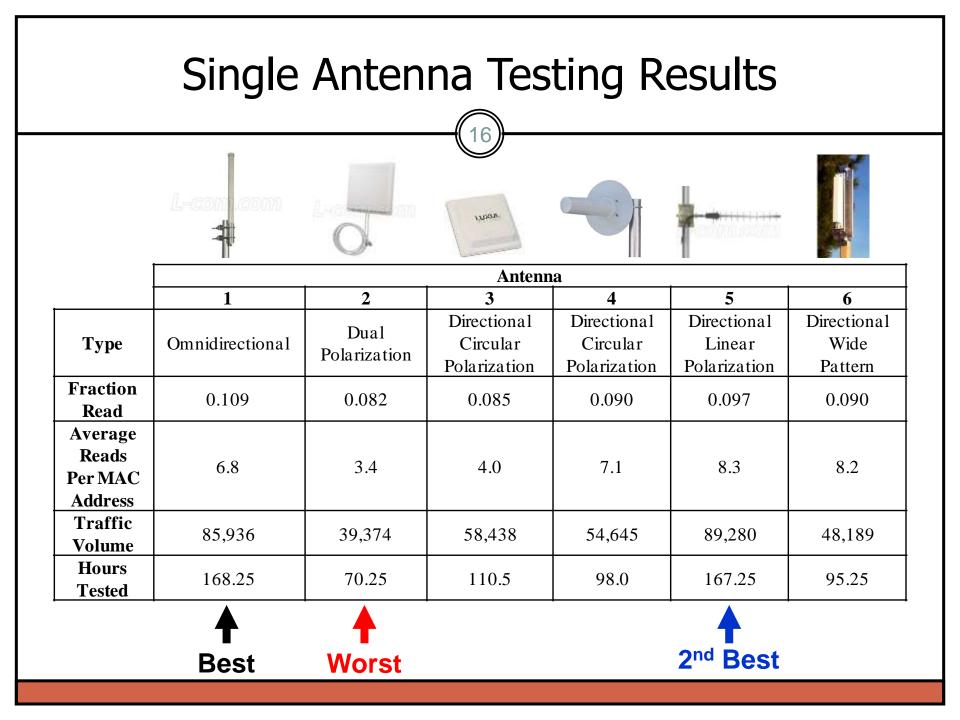

- Antennas were tested in a random order
- Traffic count data was collected
 - In each lane adjacent to the Bluetooth (BT) reader, inductive loop detectors were present and collecting traffic count data
 - Counts for every 15 minute interval
- The BT reader unit with a specific antenna collected MAC address data for a period of between three and seven days
 - Time periods dictated by availability of ODOT personnel

Data Collection and Analysis

- The antenna performance measure computed was referred to as the *fraction read*
 - Total number of unique MAC addresses read divided by the total traffic volume over the same time period
 - Some vehicles traveled past the reader multiple times
 - Some vehicles may contain more than one active BT device
- It is assumed that the fraction of vehicles with active BT devices is constant
 - A large number of vehicles (minimum 39K) passed the reader
 - No changes in laws related to cell phone use in vehicles
 - □30% of the Mac addresses were the same across different antennas
 - See slide 18

Data Collection and Analysis

- The average number of reads per MAC address was also computed
 - Total number of MAC address records over the test period (including multiple reads of the same address) divided by the total number of unique MAC addresses read
 - This measure is indicative of the total volume of data collected
 - A higher fraction read measure combined with a relatively low reads per MAC address measure seems ideal

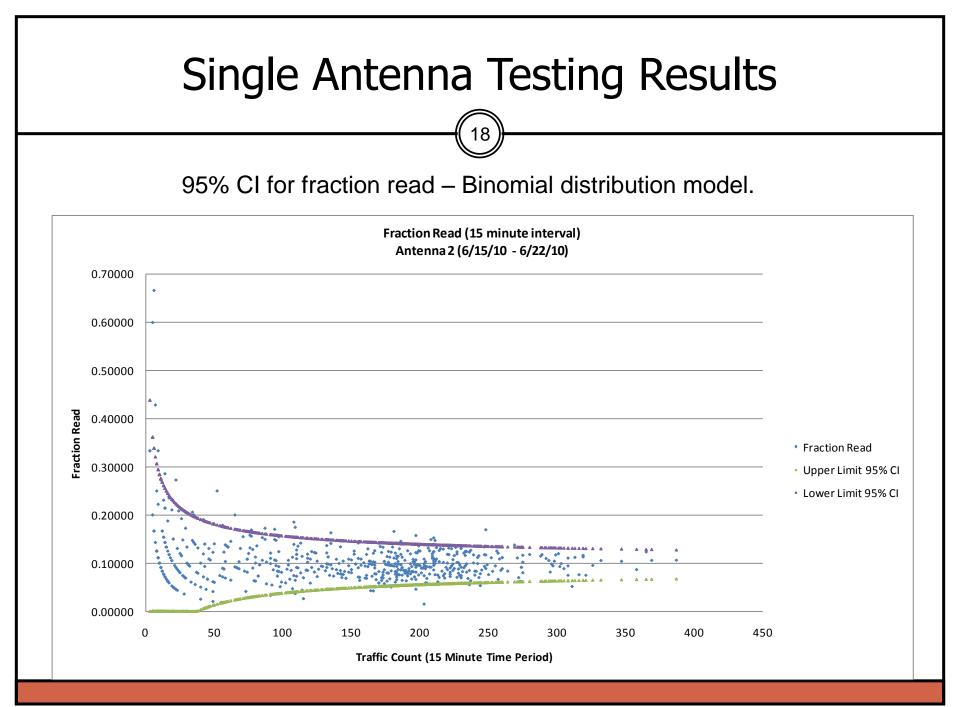

Single Antenna Testing Results

Pair-wise comparison of antenna with respect to fraction read performance

•Marascuillo procedure applied – 95% "overall" confidence level.

- 0 no significant pair-wise difference,
- 1 significant pair-wise difference.

Antenna #	1	5	4	6	3	2
1	0	1	1	1	1	1
5		0	1	1	1	1
4			0	0	0	1
6				0	0	1
3					0	0
2						0

 Tests to assess the impact of antenna characteristics on the collection of travel time samples were conducted.

Travel Time Data Collection Testing Setup

20

Test Location

• Reader & antenna installation

Reader #1

Reader #2

Travel Time Data Collection Testing Setup

- Both locations
 - Power
 - Mounting structure (reader 2 was lower with respect to the road)
 - Connection to a cellular modem
- Reader 1 was adjacent to loop detectors
- Low volume of traffic onto roads between readers

Experimental Design, Data Collection and Analysis

- The order of tests was randomized
 - Same antenna used with both readers
- Collected MAC addresses for two separate periods of between 3 and 7 days
 - Is there a difference within the same antenna type?
- Probe vehicle runs were also conducted
 - Contained an active BT device with a known MAC address and a clock synchronized with the readers
 - The time that the probe vehicle passed each reader was recorded
 - A line drawn from the reader and perpendicular to the road was used as the location where the vehicle passed the reader

- Performance measures computed for each antenna pair
 - Traffic volume (from the loop detectors)
 - The number of travel time samples computed from the collected data
 - The percentage of travel time samples obtained with respect to traffic volume
 - The average absolute percent difference in travel times (between reader #1 and reader #2) between the probe vehicle and the travel times computed for the probe vehicle from collected MAC address data

- Computing travel time samples
 - A computer program written in Visual Basic for Applications (VBA) in Microsoft Excel was used
 - General procedure
 - 1. Identify all MAC addresses detected by each reader
 - 2. Eliminate those MAC addresses not detected by both readers
 - 3. For data from a single reader, organize the MAC address data into *groups*
 - 4. Compute travel time samples from the groups of MAC addresses for each reader
 - A <u>group</u> is a collection of data records with the same MAC address sorted sequentially by time, where the time between any adjacent records is no greater than a fixed threshold
 - Within group threshold = 30 second
 - Between groups threshold = 2 minutes

 Results – Trade-off b/w sampling rate and accuracy of travel time samples

Conclusions

28

- There was no benefit realized by utilizing circularly or dual polarized antennas
- A good match between the BT reader and antenna makes a difference
 - Vertically polarized antennas with gains between 9 and 12 dBi had the best performance
 - Gain should translate into a greater coverage area with more reads but it seems to be affected by polarization.
- Collecting travel time samples
 - Narrower antenna coverage patterns translate into smaller groups
 - Accuracy of the travel time samples is more critical than sampling rate

Current Research

- Utilize Received Signal Strength Indicator (RSSI) to improve the accuracy of travel time samples computed from matched BT addresses.
- RSSI can be obtained during the inquiry procedure when MAC addresses are detected.
- RSSI is correlated to distance
 - Use RSSI measurements to select a single time-stamped MAC address from a group.
 - Use the selected MAC address to compute a travel time sample.

Current Research

30

• Testing – Does the MAC address record with the highest RSSI represent when the vehicle is close to the antenna?
